

Supplementary Figure 2: Histopathology in a case of combined LCDD and LCCN. Light microscopy showed tubular casts rimmed by macrophages. No nodular mesangial expansion is seen in the glomerulus (A). On immunofluorescence, there was no staining for kappa chains (B), while intense, diffuse linear staining of glomerular and tubular basement membranes was seen for lambda light chains (C). Tubular casts stained for lambda chains (red arrows) as compared with kappa light chains.
